

# FACTORISATION OF GERM-LIKE SERIES

SONIA L'INNOCENTE AND VINCENZO MANTOVA

**ABSTRACT.** A classical tool in the study of real closed fields are the fields  $K((G))$  of generalised power series (i.e., formal sums with well-ordered support) with coefficients in a field  $K$  of characteristic 0 and exponents in an ordered abelian group  $G$ . A fundamental result in [1] ensures the existence of irreducible series in the subring  $K((G^{\leq 0}))$  of  $K((G))$  consisting of the generalised power series with non-positive exponents.

It is an open question whether the factorisations of a series of the ring have common refinements, and whether the factorisation becomes unique after taking the quotient by the ideal generated by the non-constant monomials. In this paper, we provide a new class of irreducibles and prove some further cases of uniqueness of the factorisation.

## 1. INTRODUCTION

If  $K$  is a field and  $G$  an additive abelian ordered group, a *formal series* with *coefficients* in  $K$  and *exponents* in  $G$  is a formal sum  $a = \sum_{\gamma} a_{\gamma} t^{\gamma}$ , where  $a_{\gamma} \in K$  and  $\gamma \in G$ . We call *support* of  $a$  the set  $S_a := \{\gamma \in G : a_{\gamma} \neq 0\}$ . A formal series  $a$  is said to be a *generalised power series* if its support  $S_a$  is well-ordered. The collection of all generalised power series, denoted by  $K((G))$ , is a field with respect to the obvious operations  $+$  and  $\cdot$  defined for ordinary power series (see [3]).

When  $K$  is ordered, then  $K((G))$  has a natural order as well, obtained by stipulating that  $0 < t^{\gamma} < a$  for any  $\gamma \in G^{>0}$  and for any positive element  $a$  of the field  $K$ . Moreover, if  $K$  is real closed and  $G$  is divisible, then  $K((G))$  is real closed. Conversely, any ordered field can be represented as a subfield of  $K((G))$  for suitable  $K$  and  $G$  (in fact, we can take  $K = \mathbb{R}$ ).

For these reasons, the field  $K((G))$  is a valuable tool for the study of real closed fields. One can use them to prove, for instance, that every real closed field  $R$  has an integer part (i.e., a subring  $Z$  such that for all  $x \in R$  there exists a unique integer part  $[x] \in Z$  of  $x$  such that  $[x] \leq x < [x] + 1$ ) [5]. For example,  $\mathbb{Z} + K((G^{<0}))$  is an integer part of  $K((G))$ , where  $K((G^{<0}))$  is the subring of the series with the support contained in the negative part  $G^{<0}$  of the group  $G$ .

The ring  $\mathbb{Z} + K((G^{<0}))$  has a non-trivial arithmetic behaviour, some of which is already visible in  $K + K((G^{<0})) = K((G^{\leq 0}))$ . When  $G$  is divisible, the ring  $K((G^{\leq 0}))$  is non-noetherian, as for instance we have  $t^{-1} = t^{-\frac{1}{2}} \cdot t^{-\frac{1}{2}} = t^{-\frac{1}{4}} \cdot t^{-\frac{1}{4}} \cdot t^{-\frac{1}{4}} \cdot t^{-\frac{1}{4}} = \dots$ . However, Berarducci [1] proved that  $K((G^{\leq 0}))$  contains irreducible series, such as  $1 + \sum_n t^{-\frac{1}{n}}$ , answering a question of Conway [2]; in fact, the result implies that  $1 + \sum_n t^{-\frac{1}{n}}$  is irreducible in the ring of omnific integers, which are the natural integer part of surreal numbers.

*Key words and phrases.* Generalized power series, unique factorisation, order-value.

Both authors gratefully acknowledge the support of the project FIRB2010 “New advances in the Model theory of exponentiation” RBFR10V792, of which the first author is the principal investigator. The second author was also supported by the ERC-AdG “Diophantine Problems” 267273.

In order to state Berarducci's result, let the *order type*  $\text{ot}(a)$  of a power series  $a \in K((G^{\leq 0}))$  be the ordinal number representing the order type of its support  $S_a$ . Moreover, let  $J$  be the ideal of the series that are divisible by  $t^\gamma$  for some  $\gamma \in G^{<0}$  (as noted before for  $\gamma = -1$ , such series cannot be factored into irreducibles, since  $t^\gamma = t^{\frac{\gamma}{2}}t^{\frac{\gamma}{2}} = \dots$ ).

**Theorem 1.1** ([1, Thm. 10.5]). *If  $a \in K((\mathbb{R}^{\leq 0})) \setminus J$  (equivalently,  $a \in K((\mathbb{R}^{\leq 0}))$  not divisible by  $t^\gamma$  for any  $\gamma < 0$ ) has order type  $\omega^\alpha$  for some ordinal  $\alpha$ , then both  $a$  and  $a + 1$  are irreducible.*

This was partially strengthened by Pitteloud [6], who proved that the irreducible series of order type  $\omega$ , and in some cases  $\omega + 1$ , are actually prime. The result was obtained by constructing a function resembling a valuation but taking values into ordinal numbers.

**Definition 1.2** ([1, Def. 5.2]). For  $a \in K((G^{\leq 0}))$ , the *order-value*  $v_J(a)$  of  $a$  is:

- (1) if  $a \in J$ , then  $v_J(a) := 0$ ;
- (2) if  $a \in J + K$  and  $a \notin J$ , then  $v_J(a) := 1$ ;
- (3) if  $a \notin J + K$ , then  $v_J(a) := \min\{\text{ot}(a') : a - a' \in J + K\}$ .

The difficult key result of [1] is that for  $G = \mathbb{R}$  the function  $v_J$  is *multiplicative*.

**Theorem 1.3** ([1, Thm. 9.7]). *For all  $a, b \in K((\mathbb{R}^{\leq 0}))$  we have  $v_J(ab) = v_J(a) \odot v_J(b)$  (where  $\odot$  is Hessenberg's natural product on ordinal numbers).*

This immediately implies, for instance, that the ideal  $J$  is prime, so the quotient ring of *germs*  $K((\mathbb{R}^{\leq 0}))/J$  is an integral domain (in fact,  $J$  is prime for arbitrary choices of  $G$ , see [7]). Moreover, the function  $v_J$  is well-defined in the quotient; it follows that  $K((\mathbb{R}^{\leq 0}))/J$  has no infinite ascending chains of principal ideals, and in particular, every non-zero germ is a product of irreducible germs. The aforementioned theorem of irreducibility also follows from the multiplicative property with some modest effort.

The above comments and theorems support and motivate the following conjectures. If  $a = b_1 \cdot \dots \cdot b_n$  is a factorisation of a series  $a$ , possibly with some reducible factors, a *refinement* is another factorisation of  $a$  obtained by replacing each  $b_i$  with a further factorisation of  $b_i$ . More formally, a refinement is a factorisation  $a = c_1 \cdot \dots \cdot c_m$  such that, up to reordering  $c_1, \dots, c_m$ ,  $b_i = k_i \cdot c_{m_i+1} \cdot \dots \cdot c_{m_{i+1}}$  for some constants  $k_i \in K^*$  and some natural numbers  $0 = m_1 \leq \dots \leq m_{n+1} = m$ .

**Conjecture 1.4** (Conway [2]). *For every non-zero series  $a \in K((\mathbb{R}^{\leq 0}))$ , any two factorisations of  $a$  admit common refinements.*

For instance, it is easy to verify that for all  $\gamma < 0$ , any two factorisations of  $t^\gamma$  admit a common refinement. Similarly, any polynomial in  $t^{-\gamma}$  with coefficients in  $K$  has infinitely many factorisations, but again any two of them admit a common refinement.

**Conjecture 1.5** (Berarducci [1]). *Every non-zero germ in  $K((\mathbb{R}^{\leq 0}))/J$  admits a unique factorisation into irreducibles.*

Adapting Pitteloud's technique, we shall prove that the germs of order-value  $\omega$  are prime in  $K((\mathbb{R}^{\leq 0}))/J$ ; in particular, the germs of order-value at most  $\omega^3$  admit a unique factorisation into irreducibles, supporting Berarducci's conjecture.

**Theorems 3.3-3.4.** *All germs in  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega$  are prime. Every non-zero germ in  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\leq \omega^3$  admits a unique factorisation into irreducibles.*

Moreover, we shall isolate the notion of *germ-like* series: we say that  $a \in K((\mathbb{R}^{\leq 0}))$  is germ-like if either  $\text{ot}(a) = v_J(a)$  or  $v_J(a) > 1$  and  $\text{ot}(a) = v_J(a) + 1$  and (see Definition 4.1). The main result of [1] can be rephrased as saying that germ-like series of order-value  $\omega^{\omega^\alpha}$  are irreducible, while the main result of [6] is that germ-like series of order-value  $\omega$  are prime. Moreover, Pommersheim and Shahriari [8] proved that germ-like series of order-value  $\omega^2$  have a unique factorisation, and that some of them are irreducible.

By generalising an argument in [1], we shall see that germ-like series always have factorisations into irreducibles. Together with Pitteloud's result, we shall be able to prove that the factorisation into irreducibles of germ-like series of order-value at most  $\omega^3$  must be unique.

**Theorems 4.7-4.8.** *All non-zero germ-like series in  $K((\mathbb{R}^{\leq 0}))$  admit factorisations into irreducibles. Every non-zero germ-like series in  $K((\mathbb{R}^{\leq 0}))$  of order-value  $\leq \omega^3$  admits a unique factorisation into irreducibles.*

For completeness, we shall also verify that irreducible germs and series of order-value  $\omega^3$  do exist.

**Theorems 5.7-5.8.** *There exist irreducible germs in  $K((\mathbb{R}^{\leq 0}))/J$  and irreducible series in  $K((\mathbb{R}^{\leq 0}))$  of order-value  $\omega^3$ .*

**Further remarks.** As noted before, all the known results about irreducibility and primality of generalised power series are in fact about germ-like power series. In view of this, we propose the following conjecture, which seems to be a reasonable intermediate statement between Conway's conjecture and Berarducci's conjecture.

**Conjecture 1.6.** *Every non-zero germ-like series in  $K((\mathbb{R}^{\leq 0}))$  admits a unique factorisation into irreducibles.*

In order to treat other series that are not germ-like, we note that Lemma 4.4 and its following Corollary 4.6 suggest an alternative multiplicative order-value map whose value is the *first* term of the Cantor normal form of the order type, rather than the last infinite one. This has several consequences about irreducibility of general series; for instance, if  $P$  is the multiplicative group of the non-zero series with finite support, it implies that the localised ring  $P^{-1}K((\mathbb{R}^{\leq 0}))$  admit factorisation into irreducibles. Other consequences of the new order-value will be investigated in a future paper.

## 2. PRELIMINARIES

**2.1. Ordinal arithmetic.** This subsection is a self-contained presentation of the classical and well-known properties of ordinal arithmetic. First, let us briefly recall how ordinals can be introduced. Two (linearly) ordered sets  $X$  and  $Y$  are called ordinally similar if they are isomorphic. The order similarity is an equivalence relation and its classes are called *order types*.

An *ordinal number* is the order type of a *well-ordered* set, i.e., an ordered set with the property that any non-empty subset has a minimum. Given two ordinal numbers  $\alpha, \beta$ , we say that  $\alpha \leq \beta$  if there are two representatives  $A$  and  $B$  such that  $A \subseteq B$  and such that the inclusion of  $A$  in  $B$  is a homomorphism; we say that  $\alpha < \beta$  if  $\alpha \leq \beta$  and  $\alpha \neq \beta$ . A key observation in the theory of ordinals is that **On** itself is *well-ordered by  $\leq$* . This lets us define ordinal arithmetic by induction on  $\leq$ :

- the minimum ordinal in **On** is called *zero* and is denoted by 0;
- given an  $\alpha \in \mathbf{On}$ , the *successor*  $S(\alpha)$  of  $\alpha$  is the minimum  $\beta$  such that  $\beta > \alpha$ ;
- given a set  $A \subseteq \mathbf{On}$ , the *supremum*  $\sup(A)$  is the minimum  $\beta$  such that  $\beta \geq \alpha$  for all  $\alpha \in A$ ;

- *sum*:  $\alpha + 0 := \alpha$ ,  $\alpha + \beta := \sup_{\gamma < \beta} \{S(\alpha + \gamma)\}$ ;
- *product*:  $\alpha \cdot 0 := 0$ ,  $\alpha \cdot 1 := \alpha$ ,  $\alpha \cdot \beta := \sup_{\gamma < \beta} \{\alpha \cdot \gamma + \alpha\}$ ;
- *exponentiation*:  $\alpha^0 := 1$ ,  $\alpha^\beta := \sup_{\gamma < \beta} \{\alpha^\gamma \cdot \alpha\}$ .

One can easily verify that sum and product are associative, that the product is distributive over the sum in the second argument, and that  $\alpha^{\beta+\gamma} = \alpha^\beta \cdot \alpha^\gamma$ . Moreover, sum, product and exponentiation are strictly increasing and continuous in the second argument.

The *finite* ordinals are the ones that are represented by finite ordered sets. They can be identified with the natural numbers  $0, 1, 2, \dots$ , where ordinal arithmetic coincides with Peano's arithmetic. The ordinals that are not successors are called *limit*, and one can verify that  $\alpha$  is a limit if and only if  $\alpha \neq 0$  and  $\alpha = \sup_{\beta < \alpha} \{\beta\}$ . The smallest limit ordinal is called  $\omega$ .

The three operations admit notions of subtraction, division and logarithm. More precisely, given  $\alpha \leq \beta$ , there exist:

- a unique  $\gamma$  such that  $\alpha + \gamma = \beta$ ;
- unique  $\gamma, \delta$  with  $\delta < \alpha$  such that  $\alpha \cdot \gamma + \delta = \beta$ ;
- unique  $\gamma, \delta, \eta$  with  $\delta < \beta$ ,  $\eta < \alpha$  such that  $\beta^\gamma \cdot \delta + \eta = \alpha$ .

In particular, for all  $\alpha \in \mathbf{On}$  there is a unique finite sequence  $\beta_1 \geq \beta_2 \geq \dots \geq \beta_n \geq 0$  such that

$$\alpha = \omega^{\beta_1} + \dots + \omega^{\beta_n}.$$

The expression on the right-hand side is called *Cantor normal form* of  $\alpha$ . Given two ordinals in Cantor normal form, it is rather easy to calculate the Cantor normal form of their sum and product, using associativity, distributivity in the second argument and the following rules:

- if  $\alpha < \beta$ ,  $\omega^\alpha + \omega^\beta = \omega^\beta$ ;
- if  $\alpha = \omega^{\beta_1} + \dots + \omega^{\beta_n}$  is in Cantor normal form and  $\gamma > 0$ , then  $\alpha \cdot \omega^\gamma = \omega^{\beta_1 + \gamma}$ .

Finally, we recall that  $\mathbf{On}$  also admits different commutative operations called *Hessenberg's natural sum*  $\oplus$  and *natural product*  $\odot$ . These can be defined rather easily using the Cantor normal form. Given  $\alpha = \omega^{\gamma_1} + \omega^{\gamma_2} + \dots + \omega^{\gamma_n}$  and  $\beta = \omega^{\gamma_{n+1}} + \omega^{\gamma_{n+2}} + \dots + \omega^{\gamma_{n+m}}$  in Cantor normal form, the natural sum  $\alpha \oplus \beta$  is defined as  $\alpha \oplus \beta := \omega^{\gamma_{\pi(1)}} + \omega^{\gamma_{\pi(2)}} + \dots + \omega^{\gamma_{\pi(n+m)}}$ , where  $\pi$  is a permutation of the integers  $1, \dots, n+m$  such that  $\gamma_{\pi(1)} \geq \dots \geq \gamma_{\pi(n+m)}$ , and the natural product is defined by  $\alpha \odot \beta := \bigoplus_{1 \leq i \leq n} \bigoplus_{n+1 \leq j \leq n+m} \omega^{\gamma_i \oplus \gamma_j}$ .

**2.2. Order-value.** We now recall the definition and the basic properties of the order-value map introduced by Berarducci in [1].

Given  $a \in K((\mathbb{R}^{\leq 0}))$ , we let  $\text{ot}(a)$  be the order type of support  $S_a$  of  $a$  (recall that the support of  $a$  is a well-ordered subset of  $\mathbb{R}$ , hence  $\text{ot}(a)$  is a countable ordinal). One can verify that given two series  $a, b \in K((\mathbb{R}^{\leq 0}))$  we have:

- $\text{ot}(a + b) \leq \text{ot}(a) \oplus \text{ot}(b)$ ;
- $\text{ot}(a \cdot b) \leq \text{ot}(a) \odot \text{ot}(b)$ .

However, the above inequalities may well be strict for certain values of  $a$  and  $b$ . In order to get a better algebraic behaviour, Berarducci introduced the so called *order-value*  $v_J : K((\mathbb{R}^{\leq 0})) \rightarrow \mathbf{On}$  by considering only the 'tail' of the order type.

**Definition 2.1.** Let  $J$  be the ideal of  $K((\mathbb{R}^{\leq 0}))$  generated by the set of monomials  $\{t^\gamma : \gamma \in G^{<0}\}$ .

For every  $a \in K((\mathbb{R}^{\leq 0}))$ , the coset  $a + J \in K((\mathbb{R}^{\leq 0}))/J$  is called the *germ* of  $a$ .

*Remark 2.2.* The ideal  $J$  can also be defined by looking at the support: for every series  $a$ ,  $a \in J$  if and only if there exists  $\gamma < 0$  such that  $S_a \leq \gamma$ . In particular,

$a + J = b + J$  if and only if there exists  $\gamma < 0$  such that for all  $\delta \geq \gamma$ , the coefficients of  $t^\delta$  in  $a$  and  $b$  coincide.

**Notation 2.3.** Let  $V \subseteq K((\mathbb{R}^{\leq 0}))$  be any  $K$ -vector space. Then, let us write, for  $a, b \in K((\mathbb{R}^{\leq 0}))$ ,  $a \equiv b \pmod V$  if  $a - b \in V$ .

**Definition 2.4.** The *order-value*  $v_J : K((\mathbb{R}^{\leq 0})) \rightarrow \mathbf{On}$  is defined by:

$$v_J(b) := \begin{cases} 0 & \text{if } b \in J, \\ 1 & \text{if } b \notin J \text{ and } b \in J + K, \\ \min\{\text{ot}(c) : c \equiv b \pmod{J + K}\} & \text{otherwise.} \end{cases}$$

*Remark 2.5.* Suppose that  $a$  is not in  $J + K$  and write  $\text{ot}(a) = \omega^{\alpha_1} + \dots + \omega^{\alpha_n}$  in Cantor normal form. Then  $v_J(a)$  is precisely the last infinite term of the Cantor normal form of  $\text{ot}(a)$  (which is either  $\omega^{\alpha_{n-1}}$  or  $\omega^{\alpha_n}$ , depending on whether  $0 \in S_a$  or  $0 \notin S_a$ ). Note in particular that the order-value takes only values of the form  $\omega^\alpha$  or 0.

Furthermore, since  $a \equiv b \pmod J$  implies  $v_J(a) = v_J(b)$ , the map  $v_J$  induces an analogous order-value  $\bar{v}_J : K((\mathbb{R}^{\leq 0}))/J \rightarrow \mathbf{On}$  by defining  $\bar{v}_J(a + J) := v_J(a)$ . With a slight abuse of notation, we will use the symbol  $v_J$  for both  $v_J$  and  $\bar{v}_J$ .

The key and difficult result of [1] is that the function  $v_J$  is multiplicative.

**Proposition 2.6** ([1, Lem. 5.5 and Thm. 9.7]). *Let  $a, b \in K((\mathbb{R}^{\leq 0}))$ . Then:*

- (1)  $v_J(a + b) \leq \max\{v_J(a), v_J(b)\}$  with equality if  $v_J(a) \neq v_J(b)$ ,
- (2)  $v_J(ab) = v_J(a) \odot v_J(b)$  (multiplicative property).

The multiplicative property is the crucial ingredient that leads to the main results in [1]. For instance, it implies the following.

**Proposition 2.7** ([1, Thm. 9.8]). *The ideal  $J$  of  $K((\mathbb{R}^{\leq 0}))$  is prime.*

*Proof.* Note that  $a \in J$  if and only if  $v_J(a) = 0$ . It follows that for all  $a, b \in K((\mathbb{R}^{\leq 0}))$ , if the product  $ab$  is in  $J$ , that is,  $v_J(ab) = 0$ , then  $v_J(a) \odot v_J(b) = 0$ , which implies  $v_J(a) = 0$  or  $v_J(b) = 0$ , hence  $a \in J$  or  $b \in J$ .  $\square$

Finally, we recall some additional notions and results from [1].

**Definition 2.8.** Given  $a = \sum_{\beta} a_{\beta} t^{\beta} \in K((\mathbb{R}^{\leq 0}))$  and  $\gamma \in \mathbb{R}^{\leq 0}$ , we define:

- the *truncation* of  $a$  at  $\gamma$  is  $a_{|\gamma} := \sum_{\beta \leq \gamma} a_{\beta} t^{\beta}$ ,
- the *translated truncation* of  $a$  at  $\gamma$  is  $a^{|\gamma} := t^{-\gamma} a_{|\gamma}$ .

The equivalence class  $a^{|\gamma} + J$  is the *germ* of  $a$  at  $\gamma$ .

It turns out that translated truncations behave like a sort of ‘generalised coefficients’, as they satisfy the following equation.

**Proposition 2.9** ([1, Lem. 7.5(2)]). *For all  $a, b \in K((\mathbb{R}^{\leq 0}))$  and all  $\gamma \in \mathbb{R}^{\leq 0}$  we have:*

$$(ab)^{|\gamma} = \sum_{\delta + \varepsilon = \gamma} a^{|\delta} b^{|\varepsilon} \pmod J \quad (\text{convolution formula}).$$

### 3. PRIMALITY IN $K((\mathbb{R}^{\leq 0}))/J$

Pitteldoud [6] proved that the series of order type  $\omega$  or  $\omega + 1$  and order-value  $\omega$  are *prime*. In this section, we adopt the same strategy to prove that every germ  $a \in K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega$  is prime.

Following [6, p. 1209], we introduce some additional  $K$ -vector spaces.

**Definition 3.1** ([6, p. 1209]). For  $\alpha \in \mathbf{On}$  let  $J_{\omega^\alpha} := \{a \in K((\mathbb{R}^{\leq 0})) : v_J(a) < \omega^\alpha\}$ .

Moreover, we say that  $b \mid a \pmod{J_{\omega^\alpha}}$  if there exists  $c \in K((\mathbb{R}^{\leq 0}))$  such that  $a \equiv bc \pmod{J_{\omega^\alpha}}$ .

For instance,  $J_{\omega^0} = J$  and  $J_{\omega^1} = J + K$ . Note that  $J_{\omega^\alpha}$  is just a  $K$ -vector space. By the multiplicative property, one can easily verify that  $J_{\omega^\alpha}$  is closed under multiplication if and only if  $\alpha = \omega^\beta$  for some  $\beta$ , and it is an ideal if and only if  $\alpha = 0$ .

Let  $a, b, c, d \in K((\mathbb{R}^{\leq 0}))$  satisfy  $ab = cd$  and  $v_J(a) = \text{ot}(a) = \omega$ . Pitteloud proved that either  $a \mid c$  or  $a \mid d$  in  $K((\mathbb{R}^{\leq 0}))$  (where  $a \mid c$  means  $a$  divides  $c$ ) by analysing the related equation  $a^k b = c^l d$  (with  $k, l > 0$ ). More precisely, he proved the following:

**Proposition 3.2** ([6, Prop. 3.2]). *Let  $a, b, c, d$  in  $K((\mathbb{R}^{\leq 0}))$  be such that  $v_J(a) = \omega$  and assume that  $a^k b = c^l d \pmod{J_{v_J(a^k b)}}$  with  $k, l > 0$ . Then either  $a \mid c \pmod{J_{v_J(c)}}$  or  $a \mid d \pmod{J_{v_J(d)}}$ .*

Starting from this proposition, we can prove the following result.

**Theorem 3.3.** *All germs in  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega$  are prime.*

*Proof.* Let  $A = a + J$ ,  $B = b + J$ ,  $C = c + J$  and  $D = d + J$  be non-zero germs of  $K((\mathbb{R}^{\leq 0}))/J$  such that  $v_J(A) = \omega$  and  $AB = CD$ . We claim that  $A \mid C$  or  $A \mid D$ . We work by induction on  $v_J(AB)$ .

Note that  $v_J(ab - cd) = v_J(AB - CD) = 0$ , so there exists  $j \in J$  such that  $ab = cd + j$ . Since  $v_J(j) = 0 < \omega = v_J(a) \leq v_J(ab)$ , we have in fact  $ab = cd \pmod{J_{v_J(ab)}}$ . By Proposition 3.2, either  $a \mid c \pmod{J_{v_J(c)}}$  or  $a \mid d \pmod{J_{v_J(d)}}$ .

Since  $C$  and  $D$  have a symmetric role, we may assume to be in the former case. Then there are  $e, c' \in K((\mathbb{R}^{\leq 0}))$  such that  $c = ae + c'$  with  $v_J(c') < v_J(c)$ . In turn, we have

$$ab = cd + j = (ae + c')d + j$$

and in particular

$$a(b - ed) = c'd + j.$$

Let  $B' := (b - ed) + J$ ,  $C' := c' + J$ ,  $E := e + J$ . The above equation means that  $AB' = C'D$ . Now note that  $v_J(AB') = v_J(C'D) < v_J(CD) = v_J(AB)$ . Therefore, by inductive hypothesis, either  $A \mid C'$  or  $A \mid D$ . In the latter case, we are done. In the former case, we just recall that  $C = AE + C'$ , so  $A \mid C$ , as desired.  $\square$

**Theorem 3.4.** *Every non-zero germ in  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\leq \omega^3$  admits a unique factorisation into irreducibles.*

*Proof.* If  $v_J(A) = \omega$ , then  $A$  is prime and therefore irreducible by Theorem 3.3.

If  $v_J(A) = \omega^2$  or  $\omega^3$ , then  $A$  is either irreducible or equal to  $A = BC$  with  $v_J(B), v_J(C) < v_J(A)$ . We assume to be in the latter case. Since  $v_J(B) \odot v_J(C) = v_J(A)$ , we must have that either  $v_J(B) = \omega$  or  $v_J(C) = \omega$ ; by symmetry, we may assume that  $v_J(B) = \omega$ , and in particular that  $B$  is prime.

If  $A$  has another factorisation into irreducibles, then  $B$  must divide one of the factors, and in particular it must be equal to one of the factors up to a unit. The product of the remaining factors has either order-value  $\omega^2$  or  $\omega$ ; in both cases we repeat the argument and we are done.  $\square$

#### 4. GERM-LIKE SERIES

Unfortunately, even if a series in  $K((\mathbb{R}))^{\leq 0}$  has an irreducible germ, it may well be reducible. This implies that the results on germs cannot be lifted automatically

to all series. On the other hand, there are some series which behave similarly enough to germs so that the same techniques can be applied to them.

**Definition 4.1.** We say that an  $a \in K((\mathbb{R}^{\leq 0}))$  is *germ-like* if either  $\text{ot}(a) = v_J(a)$  or  $v_J(a) > 1$  and  $\text{ot}(a) = v_J(a) + 1$ .

We shall prove that if a product of non-zero series is germ-like, then the series themselves are germ-like. For this, we recall the following definition from [1].

**Definition 4.2.** Given  $a \in K((\mathbb{R}^{\leq 0}))$ , let  $\alpha = \max\{v_J(a^{|\gamma|}) : \gamma \in \mathbb{R}^{\leq 0}\}$ . The *critical point*  $\text{crit}(a)$  of  $a$  is the smallest  $\gamma \in \mathbb{R}^{\leq 0}$  such that  $v_J(a^{|\gamma|}) = \alpha$ .

Proving that a critical point always exists is not difficult, and we refer to [1, §10] for the relevant details.

**Lemma 4.3.** If  $a \in K((\mathbb{R}^{\leq 0}))$ ,  $a$  is germ-like if and only if  $\text{crit}(a) = 0$ .

*Proof.* First of all, we note that if  $a \in J$ , then  $v_J(a) = 0$ ; in this case, we just note that  $\text{ot}(a) = 0$  if and only if  $a = 0$ , and the conclusion follows trivially. Similarly, if  $a \in J + K$  but  $a \notin J$ , then  $v_J(a) = 1$ , and clearly  $\text{ot}(a) = 1$  if and only if  $a \in K^*$ , proving again the conclusion.

Now assume that  $a \notin J + K$ . Recall that in this case  $v_J(a)$  is the last infinite term of the Cantor normal form of  $\text{ot}(a)$  (in particular,  $v_J(a) > 1$ ; see 2.5). Therefore,  $\text{ot}(a) = v_J(a)$  holds if and only if the Cantor normal form of  $\text{ot}(a)$  is  $\omega^\alpha$  for some  $\alpha \in \mathbf{On}$ . Similarly,  $v_J(a) = \text{ot}(a) + 1$  holds if and only if the Cantor normal form of  $\text{ot}(a)$  is  $\omega^\alpha + 1$  for some  $\alpha \in \mathbf{On}$ .

If  $\text{ot}(a)$  is  $\omega^\alpha$  or  $\omega^\alpha + 1$ , since  $a \notin J + K$ , we have  $\text{ot}(a^{|\gamma|}) < \omega^\alpha$  for all  $\gamma \in \mathbb{R}^{< 0}$ . In particular,  $v_J(a^{|\gamma|}) \leq \text{ot}(a^{|\gamma|}) < \omega^\alpha = v_J(a)$  for all  $x \in \mathbb{R}^{< 0}$ , hence  $\text{crit}(a) = 0$ .

On the other hand, if the Cantor normal form of  $\text{ot}(a)$  is  $\omega^{\beta_1} + \dots + \omega^{\beta_k}$  or  $\omega^{\beta_1} + \dots + \omega^{\beta_k} + 1$ , with  $k > 1$  and  $\beta_k > 0$ , let  $\gamma \in \mathbb{R}^{< 0}$  be the minimum real number such that  $\text{ot}(a^{|\gamma|}) \geq \omega^{\beta_1}$ . It is easy to verify that  $v_J(a^{|\gamma|}) = \omega^{\beta_1}$  and in fact that  $\gamma = \text{crit}(a)$ . Since  $v_J(a) = \omega^{\beta_k} \leq \omega^{\beta_1} \leq v_J(a^{|\gamma|})$ , it follows that  $\gamma = \text{crit}(a) < 0$ , as desired.  $\square$

The following lemma is inspired by [1, §10].

**Lemma 4.4.** If  $b, c$  are non-zero series of  $K((\mathbb{R}^{\leq 0}))$ , then

- (1)  $\text{crit}(bc) = \text{crit}(b) + \text{crit}(c)$ ;
- (2)  $v_J((bc)^{|\text{crit}(bc)|}) = v_J(b^{|\text{crit}(b)|}) \odot v_J(c^{|\text{crit}(c)|})$ .

*Proof.* We proceed as in [1, Lemma 10.4]. Let  $\gamma = \text{crit}(b)$  and  $\delta = \text{crit}(c)$ . By the convolution formula, for any  $\varepsilon \in \mathbb{R}^{\leq 0}$  we have

$$(bc)^{|\varepsilon|} \equiv \sum_{\gamma' + \delta' = \varepsilon} b^{|\gamma'|} c^{|\delta'|} \pmod{J}.$$

It follows at once that  $v_J((bc)^{|\varepsilon|}) \leq v_J(b^{|\gamma|}) \odot v_J(c^{|\delta|})$ , and if the equality is attained then for some  $\gamma', \delta'$  such that  $\gamma' + \delta' = \varepsilon$  we have  $v_J(b^{|\gamma'|}) = v_J(b^{|\gamma|})$  and  $v_J(c^{|\delta'|}) = v_J(c^{|\delta|})$ . In particular, if the equality holds then  $\varepsilon = \gamma' + \delta' \geq \gamma + \delta$ .

On the other hand,

$$(bc)^{|\gamma + \delta|} \equiv b^{|\gamma|} c^{|\delta|} + \sum_{\gamma' + \delta' = \gamma + \delta, \gamma' < \gamma} b^{|\gamma'|} c^{|\delta'|} + \sum_{\gamma' + \delta' = \gamma + \delta, \delta' < \delta} b^{|\gamma'|} c^{|\delta'|} \pmod{J}.$$

It immediately follows that  $v_J((bc)^{|\gamma + \delta|}) = v_J(b^{|\gamma|} c^{|\delta|}) = v_J(b^{|\gamma|}) \odot v_J(c^{|\delta|})$ . Therefore,  $\text{crit}(bc) = \gamma + \delta$ , proving both conclusions.  $\square$

**Corollary 4.5.** Let  $a, b, c \in K((\mathbb{R}^{\leq 0}))$  be non-zero series with  $a = bc$ . Then  $a$  is germ-like if and only if  $b$  and  $c$  are germ-like.

*Proof.* By Lemmas 4.3, 4.4, it suffices to note that  $\text{crit}(a) = \text{crit}(b) + \text{crit}(c)$ , so  $\text{crit}(a) = 0$  if and only if  $\text{crit}(b) = \text{crit}(c) = 0$ .  $\square$

**Corollary 4.6.** *The function  $a \mapsto v_J(a^{|\text{crit}(a)|})$  is multiplicative.*

**Theorem 4.7.** *All non-zero germ-like series in  $K((\mathbb{R}^{\leq 0}))$  admit factorisations into irreducibles.*

*Proof.* We prove the conclusion by induction on  $v_J(a)$ . If  $v_J(a) = 1$ , then we must have  $\text{ot}(a) = v_J(a) = 1$ , which implies that  $a \in K$ , and the conclusion follows trivially. If  $v_J(a) > 1$ , then either  $a$  is irreducible, in which case we are done, or  $a = bc$  for some  $b, c \in K((\mathbb{R}^{\leq 0})) \setminus K$ . By Corollary 4.5,  $b$  and  $c$  are germ-like. If  $v_J(b) = 1$ , then by the previous argument we have  $b \in K$ , a contradiction, hence  $v_J(b) > 1$ ; similarly, we deduce that  $v_J(c) > 1$  as well. By the multiplicative property, it follows that  $v_J(b), v_J(c) < v_J(a)$ ; by induction,  $b$  and  $c$  have a factorisation into irreducibles, and we are done.  $\square$

**Theorem 4.8.** *Every non-zero germ-like series in  $K((\mathbb{R}^{\leq 0}))$  of order-value  $\leq \omega^3$  admits a unique factorisation into irreducibles.*

*Proof.* Let  $a \in K((\mathbb{R}^{\leq 0}))$  be a germ-like series of order value  $v_J(a) \leq \omega^3$ . Suppose that  $a$  has a non-trivial factorisation  $a = bc$ . By the multiplicative property, and possibly by swapping  $b$  and  $c$ , we may assume  $v_J(b) \leq \omega$ .

If  $v_J(b) = 1$ , then  $\text{ot}(b) = 1$ , hence  $b \in K$ , contradicting the hypothesis that the factorization is non-trivial. It follows that  $v_J(b) = \omega$ . Since  $a$  is germ-like,  $b$  is also germ-like, hence  $\text{ot}(b) = \omega$  or  $\text{ot}(b) = \omega + 1$ , in which case  $b$  is prime by [6, Thm. 3.3]. Once we have a prime factor, one can deduce easily that the factorisation is unique, as in the proof of Theorem 3.4.  $\square$

Moreover, we observe that irreducible germs do lift to irreducible germ-like series.

**Proposition 4.9.** *Let  $a \in K((\mathbb{R}^{\leq 0}))$  be germ-like. If the germ  $a + J$  of  $a$  is irreducible in  $K((\mathbb{R}^{\leq 0}))/J$ , then  $a$  is irreducible in  $K((\mathbb{R}^{\leq 0}))$ .*

*Proof.* Suppose that  $a = bc$ . Since  $a + J$  is irreducible, it follows that one of  $b + J$  or  $c + J$  is a unit in  $K((\mathbb{R}^{\leq 0}))/J$ , say  $b + J$ . By the multiplicative property, it follows that  $v_J(b) = 1$ . Since  $b$  is germ-like we have  $\text{ot}(b) = 1$ , which implies that  $b \in K^*$ , hence that  $b$  is a unit in  $K((\mathbb{R}^{\leq 0}))$ , as desired.  $\square$

*Remark 4.10.* In general, the converse does not hold. Indeed, let  $a, b$  be two germ-like series of order-value  $\omega$ . By [8, Cor. 3.4], for all  $\gamma \in \mathbb{R}^{< 0}$  except at most countably many,  $ab + t^\gamma$  is irreducible, while of course its germ  $ab + t^\gamma + J = ab + J$  is reducible.

## 5. IRREDUCIBLES OF ORDER-VALUE $\omega^3$

We conclude by showing that there are several irreducible elements in both  $K((\mathbb{R}^{\leq 0}))$  and  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega^3$ . We follow a strategy similar to the one of [8].

**Lemma 5.1.** *Let  $a, b \in K((\mathbb{R}^{\leq 0}))$ . If  $a \equiv b \pmod{J_{\omega^{\alpha+1}}}$ , then for all  $\gamma < 0$  sufficiently small we have  $a^{|\gamma|} \equiv b^{|\gamma|} \pmod{J_{\omega^\alpha}}$ .*

*Proof.* Let  $c = a - b$ , so that  $v_J(c) < \omega^{\alpha+1}$ . Then for all sufficiently small  $\gamma < 0$  we have  $v_J(c^{|\gamma|}) < v_J(c) \leq \omega^\alpha$ . Since  $a^{|\gamma|} - b^{|\gamma|} = c^{|\gamma|}$ , we have  $a^{|\gamma|} \equiv b^{|\gamma|} \pmod{J_{\omega^\alpha}}$ .  $\square$

Given  $a \in K((\mathbb{R}^{\leq 0}))$ , we let  $V_\gamma(a)$  be the  $K$ -linear space generated by all the germs of  $a$  between  $\gamma$  and 0, modulo  $J + K$ ; formally,

$$V_\gamma(a) := \text{span}_K\{a^{|\delta|} + J + K : \gamma < \delta < 0\} \subseteq K((\mathbb{R}^{\leq 0}))/J + K.$$

We let  $V(a)$  be the intersection of all the  $V_\gamma(a)$ 's:

$$V(a) := \bigcap_{\gamma < 0} V_\gamma(a).$$

*Remark 5.2.* If  $a \equiv b \pmod{J}$ , then  $V_\gamma(a) = V_\gamma(b)$  for all sufficiently small  $\gamma \leq 0$ , so  $V(a) = V(b)$ .

**Proposition 5.3.** *Let  $a, b, c \in K((\mathbb{R}^{\leq 0}))$  be such that  $a \equiv bc \pmod{J_{\omega^2}}$  and  $v_J(b) = v_J(c) = \omega$ . Then  $\dim(V(a)) \leq 2$ .*

*Proof.* By Lemma 5.1, for all  $\gamma < 0$  sufficiently small we have  $a^{|\gamma|} \equiv (bc)^{|\gamma|} \equiv b^{|\gamma|}c + bc^{|\gamma|} \pmod{J_\omega = J + K}$ . Moreover, when  $\gamma < 0$  is sufficiently small we have  $b^{|\gamma|}, c^{|\gamma|} \in J + K$ ; in other words,  $b^{|\gamma|} = k_b + j_b$ ,  $c^{|\gamma|} = k_c + j_c$  for some  $k_b, k_c \in K$  and  $j_b, j_c \in J$ . It follows that when  $\gamma < 0$  is sufficiently small we have

$$a^\gamma \equiv k_b c + k_c b + j_b c + j_c b \equiv k_b c + k_c b \pmod{J + K}.$$

Therefore,  $V(a)$  is generated as  $K$ -vector space by  $b + J + K$  and  $c + J + K$ , hence  $\dim(V(a)) \leq 2$ .  $\square$

In order to find a sufficient criterion for irreducibility of series of order-value  $\omega^3$ , we picture a series  $a \in K((\mathbb{R}^{\leq 0}))$  of order-value  $\omega^{\alpha+1}$  as if it were a series of order-value  $\omega$  with coefficients that are themselves series of order-value  $\omega^\alpha$ . In other words, we describe  $a$  as the sum of  $\omega$  series of order-value  $\omega^\alpha$ .

**Definition 5.4.** Let  $\alpha \in \mathbf{On}$  and  $a \in K((\mathbb{R}^{\leq 0}))$  such that  $v_J(a) = \omega^{\alpha+1}$ . We say that  $\gamma \in S_a$  is a *big point* of  $a$  if  $v_J(a^{|\gamma|}) = \omega^\alpha$ .

We can use big points to give the following sufficient criterion for the irreducibility of a series in  $K((\mathbb{R}^{\leq 0}))$  of order-value  $\omega^3$ .

**Proposition 5.5.** *Let  $a, b, c \in K((\mathbb{R}^{\leq 0}))$  be such that  $a \equiv bc \pmod{J}$ ,  $v_J(b) = \omega$  and  $v_J(c) = \omega^2$ . Let  $\gamma, \delta$  be two big points of  $a$ . Then there exist  $r, s \in K$ , not both zero, such that  $\dim(V(ra^{|\gamma|} + sa^{|\delta|})) \leq 2$ .*

*Proof.* We have

$$a^{|\gamma|} \equiv b^{|\gamma|}c + bc^{|\gamma|} \pmod{J_{\omega^2}}, \quad a^{|\delta|} \equiv b^{|\delta|}c + bc^{|\delta|} \pmod{J_{\omega^2}}.$$

If  $b^{|\gamma|} = b^{|\delta|} = 0$ , then we can take  $r = 1, s = 0$  and apply Proposition 5.3 to obtain the conclusion. Otherwise, we have

$$b^{|\delta|}a^{|\gamma|} - b^{|\gamma|}a^{|\delta|} \equiv b(b^{|\delta|}c^{|\gamma|} - b^{|\gamma|}c^{|\delta|}) \pmod{J_{\omega^2}}.$$

Let  $r := b^{|\delta|}$ ,  $s := -b^{|\gamma|}$ . By the above equation and Proposition 5.3 we get  $V(ra^{|\gamma|} + sa^{|\delta|}) \leq 2$ , as desired.  $\square$

It is not difficult to construct several germs  $a \in K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega^3$  such that the condition

$$\dim(V(ra^{|\gamma|} + sa^{|\delta|})) > 2 \tag{*}$$

is satisfied for all  $r, s \in K$  not both zero and for all distinct big points  $\gamma \neq \delta$  of  $a$ . In particular, they are all irreducible. Indeed, we observe the following.

**Lemma 5.6.** *Let  $(a_i \in K((\mathbb{R}^{\leq 0}))) : i \in \mathbb{N}$  be a sequence of series of order-value  $\omega^\alpha$ , and let  $(\gamma_i \in \mathbb{R}^{< 0} : i \in \mathbb{N})$  be a strictly increasing sequence of negative real numbers such that  $\lim_{i \rightarrow \infty} \gamma_i = 0$ . Then there exists  $a \in K((\mathbb{R}^{\leq 0}))$  with  $v_J(a) = \omega^{\alpha+1}$  such that  $a^{|\gamma_i|} \equiv a_i \pmod{J}$  for all  $i \in \mathbb{N}$ .*

*Proof.* First of all, we may assume that  $S_{a_{i+1}} > \gamma_i - \gamma_{i+1}$  for all  $i \in \mathbb{N}$ . Indeed, if this is not the case, it suffices to replace  $a_{i+1}$  with the series  $a_{i+1} - (a_{i+1})_{|\gamma_i - \gamma_{i+1}} \equiv a_{i+1} \pmod{J}$ . After this reduction, we define

$$a := \sum_{i \in \mathbb{N}} t^{\gamma_i} a_i.$$

Since  $S_{t^{\gamma_{i+1}} a_{i+1}} > \gamma_i$ , we have

$$a^{|\gamma_i} = \sum_{j \leq i} t^{\gamma_j - \gamma_i} a_j \equiv a_i \pmod{J}.$$

□

**Theorem 5.7.** *There exist irreducible germs in  $K((\mathbb{R}^{\leq 0}))/J$  of order-value  $\omega^3$ .*

*Proof.* Let  $\Omega$  be any countable set of series of order-value  $\omega$  with pairwise disjoint supports. Clearly,  $\Omega$  is a  $K$ -linearly independent set. Moreover, it is  $K$ -linearly independent even modulo the vector space  $J + K$ . Let  $a_i$ , for  $i \in \mathbb{N}$ , be some enumeration of  $\Omega$ , and take a strictly increasing sequence  $(\gamma_i \in \mathbb{R}^{< \omega} : i \in \mathbb{N})$  such that  $\lim_{i \rightarrow \infty} \gamma_i = 0$ .

By Lemma 5.6, there are series  $b_i$  of order-value  $\omega^2$  such that

$$b_i^{|\gamma_{3j+k}} \equiv a_{3i+k} \pmod{J}$$

for all  $i, j \in \mathbb{N}$  and  $k \in \{0, 1, 2\}$ . By construction,

$$V(b_i) = \text{span}_K\{a_{3i} + J + K, a_{3i+1} + J + K, a_{3i+2} + J + K\},$$

so that  $\dim(V(b_i)) = 3$ .

By Lemma 5.6 again, there exists  $c$  of order-value  $\omega^3$  such that

$$c^{|\gamma_i} \equiv b_i \pmod{J}.$$

Take any  $r, s \in K$  not both zero. By construction,

$$V(rc^{|\gamma_i} + sc^{|\gamma_j}) = \text{span}_K\{ra_{3i} + sa_{3j} + J + K, ra_{3i+1} + sa_{3j+1} + J + K, ra_{3i+2} + sa_{3j+2} + J + K\}.$$

It clearly follows that for all  $i \neq j$  we have

$$\dim(V(rc^{|\gamma_i} + sc^{|\gamma_j})) = 3.$$

By Proposition 5.5, it follows that  $c + J$  is irreducible. □

**Theorem 5.8.** *There exist irreducible series in  $K((\mathbb{R}^{\leq 0}))$  of order-value  $\omega^3$ .*

*Proof.* By Theorem 5.7, there exist series  $c$  of order-value  $\omega^3$  such that  $c + J$  is irreducible. Up to replacing  $c$  with  $c - c_{|\gamma}$  for a suitable  $\gamma \in \mathbb{R}^{< 0}$ , we may directly assume that  $c$  is germ-like. By Proposition 4.9,  $c$  is irreducible. □
